Introduction to Price Subsidy Mechanics

What is ML Pricing and how does the price subsidy work?

Example for Allegro Ceny program

Wełna mineralna szklana Eurowool 100 mm

4,87 ★★★★★ 90 ocen i 12 recenzji

Stan: Nowy

**WEŁNA ATESTOWANA MINERALNA
MATA SZKLANA EUROWOOL 0,039
10CM 10,8M2**

176,00 zł SMART

(16,30 zł/m²)

Solution plan and challenges

Modeling & Optimization

We ideated two major components:

- **MODELING** – predict expected demand given the offer’s features, including price
- **OPTIMIZATION** – optimize discount levels within limited budget

Product	Offer	...	Price
123	455	...	105
123	777	...	47
...		...	
789	990	...	28

MODELING

OPTIMIZATION

Offer	EP* (2%)	EP* (4%)	...	EP* (20%)
455	-2	0	...	1
777	50		...	
...			...	
990	30		...	28

$EP(n\%)$ = estimated profit from applying an $n\%$ discount.

Solve Knapsack problem:

maximize expected GMV/profit/...

with constraints:

budget, one offer per product etc.

Challenge 1 – it is easy to discount non-profitably

Extra care required not to burn money

Wełna mineralna szklana Eurowool 100 mm

PORÓWNAJ 18 OFERT TEGO PRODUKTU

10% price discount → 77% fee lost

Challenge 2 – Allegro is a marketplace, offers are not independent

- Demand on offers is non-i.i.d. – “sales boost” on discounted offer may come from cannibalizing other offers.
- Hence we added price-rank related features for offer-level modeling, and established that the discounts will be selected based on the total impact on all offers of the same product...
- ... but this created another challenge – of defining “the same product”...
- We rely on Allegro’s Productization (a separate project on its own).
- Product perspective brings in yet another issue: there’s an abundance of variants – multipacks, sets etc, which cannibalize each other only partially, depending on the customer needs.
- You can see how moving from *the data* to *the dataset ready for model fitting* seems to be a struggle to select the *least imperfect solution*... :)

Challenge 3 – Evaluation metrics analysis paralysis

Assessing the performance of demand forecasting models:

- absolute error metrics bias towards products with high demand (e.g. products that sell in thousands daily, as opposed to singular sales)
- relative error metrics (MAPE etc.) bias towards low demand products, zero-sales weighing the most
- we really mostly care about business performance – profitably generating non-cannibalized sales...
- we never found a “winner in all metrics”, at some plateau point moved towards experimentation and measuring business impact.

Lesson learned: real world experimentation can get you unstuck and help deliver value much faster than over analyzing.

Challenge 4 – Optimizer impact on metrics

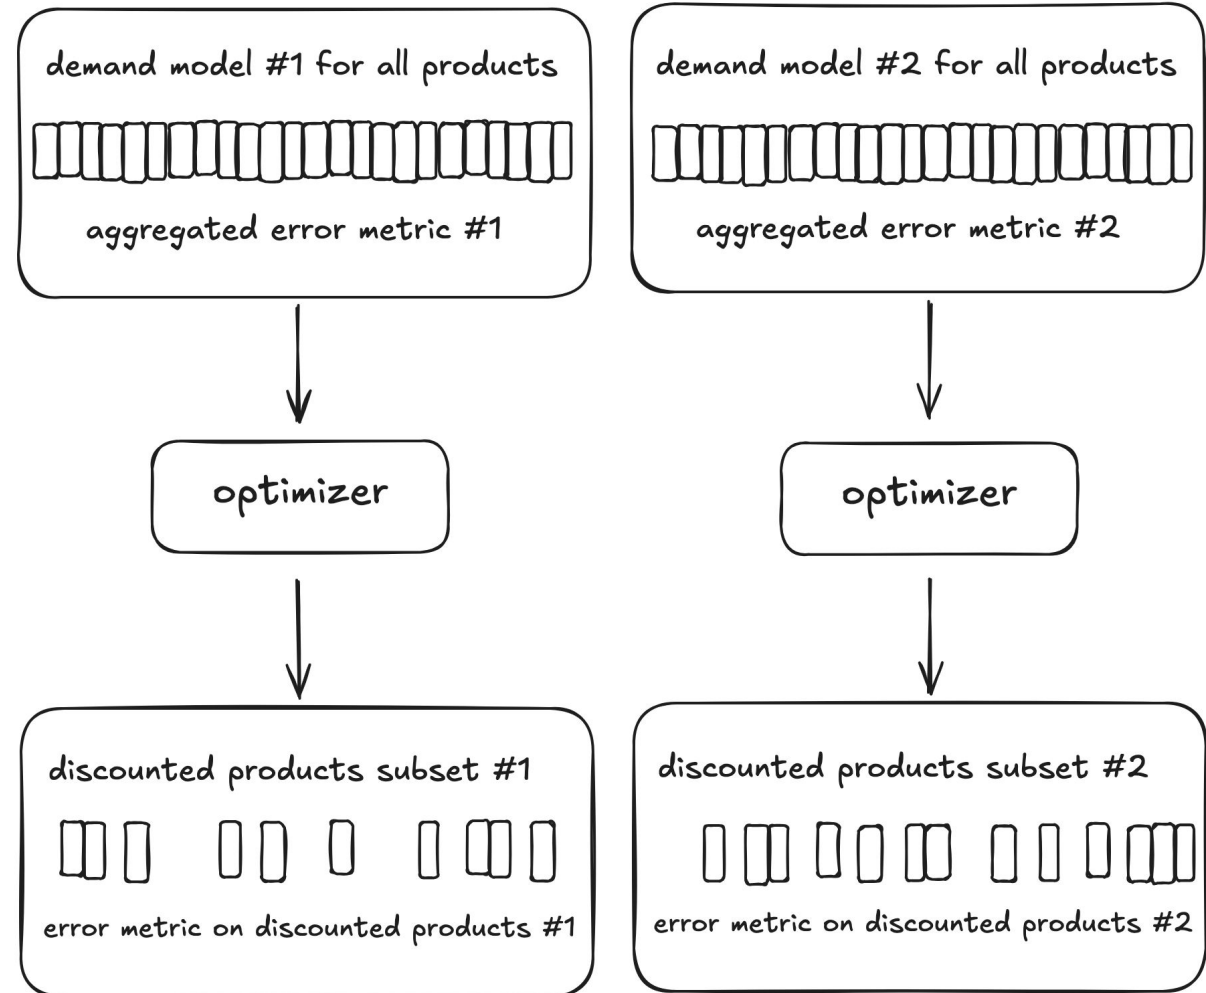

Discount Optimizer on top of model predictions makes the model selection even more difficult.

Optimizer acts as a filter selecting the “best discount candidates” according to model predictions.

It's not impossible that you'll have Model #1 better than Model #2 in every aggregated error metric, but worse on the subset of products finally selected for discount 🙄

You can't estimate the final performance while looking at the model metrics alone and not moving to the last step in the downstream task.

Lesson learned: Model metrics are helpful, but not conclusive. Downstream task performance is conclusive.

Challenge 5 – estimating causal interventional effect

By default, most observational-data based regression ML models estimate:

$$P(Y|X = x)$$

... but here we're interested in (using Pearl's *do-calculus* notation):

$$P(Y|\text{do}(X = x))$$

... and these two **are not the same!**

Toy example. Consider:

$$P(\text{water boils} \mid \text{thermometer shows } 100^\circ\text{C})$$

vs

$$P(\text{water boils} \mid \text{we manually set thermometer to } 100^\circ\text{C})$$

Our approach

Keeping “good” and removing “bad” (biasing) features (“controls”) based on causality theory.

Main point: more features will generally help you with observational prediction, but may harm interventional effect estimation. Select them carefully!

A Crash Course in Good and Bad Controls

journals.sagepub.com/home/smr

Example – day of the week

P_t – Price at time t

Q_t – Demand at time t

F_t – Day of the week

Example – day of the week

P_t – Price at time t

Q_t – Demand at time t

F_t – Day of the week

Assume:

- day of the week influences the demand
- the merchants don't change prices according to weekday.

Example – day of the week

P_t – Price at time t

Q_t – Demand at time t

F_t – Day of the week

Assume:

- day of the week influences the demand
- the merchants don't change prices according to weekday.

It's a **good control** ("model 8" in the paper).

Does not introduce bias in estimation of $P \rightarrow Q$, but (possibly) explains some variations of Q making this estimation more "sample-efficient".

Example 2 – lagged demand

P_t – Price at time t

Q_t – Demand at time t

Example 2 – lagged demand

P_t – Price at time t

Q_t – Demand at time t

Example 2 – lagged demand

P_t – Price at time t

Q_t – Demand at time t

U_t – Unobserved confounder – hidden merchant state

Bad control example – lagged demand

P_t – Price at time t

Q_t – Demand at time t

U_t – Unobserved confounder – hidden merchant state

V_t – Unobserved confounder – hidden market state

Bad control example – lagged demand

P_t – Price at time t

Q_t – Demand at time t

U_t – Unobserved confounder – hidden merchant state

V_t – Unobserved confounder – hidden market state

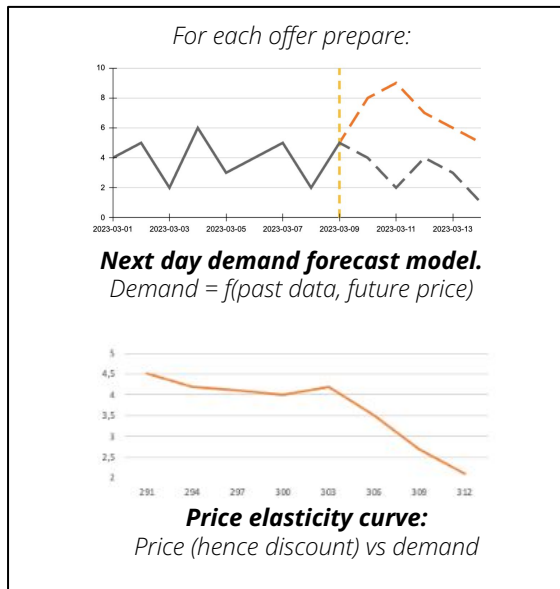

Bad control, (“model 7” in the paper), a.k.a M-bias.

Controlling for Q_{t-1} biases estimation of $P_t \rightarrow Q_t$.

Caveat – we could add P_{t-1} to close the path again, but that’s strongly correlated with P_t and generates even more issues

Final setup – wrap-up

MODELING

OPTIMIZATION

Offer	EP* (2%)	EP* (4%)	...	EP* (20%)
455	-2	0	...	1
777	50		...	
...			...	
990	30		...	28

$EP(n\%)$ = estimated profit from applying an $n\%$ discount.

Solve Knapsack problem:

maximize expected GMV/profit/...

with constraints:

budget, one offer per product etc.

Linear programming-based solver

Tweedie regression (internal upgraded implementation based on sklearn)

Features relate to:

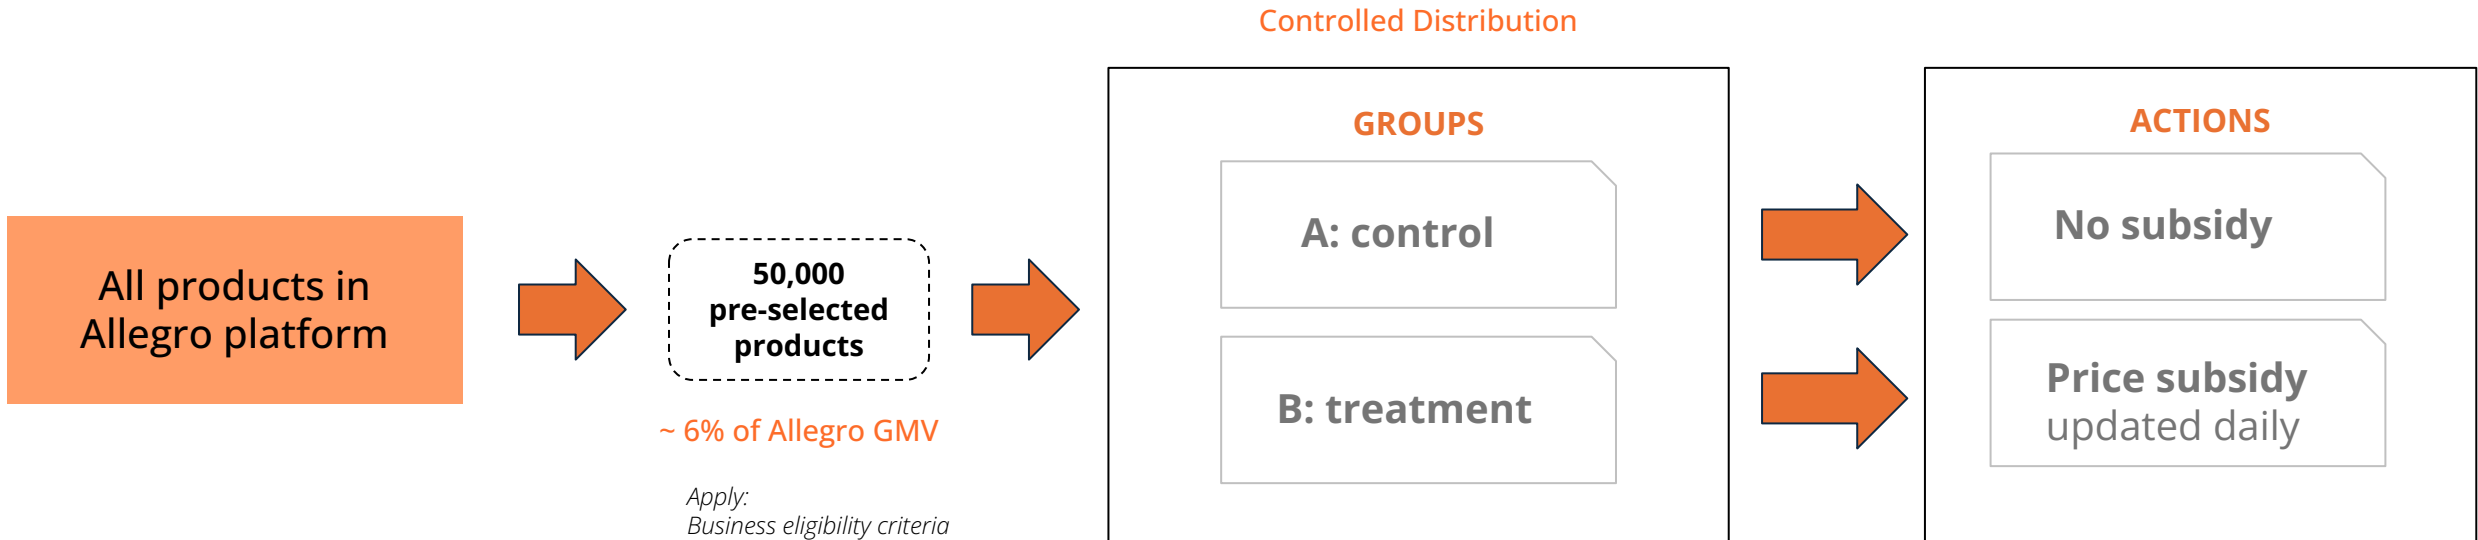

- price, price-rank relative to other offers
- offer and product quality
- delivery and other badges visible by customer
- merchant quality
- calendar context

Experimentation

Experimental setup

Product level A/B testing

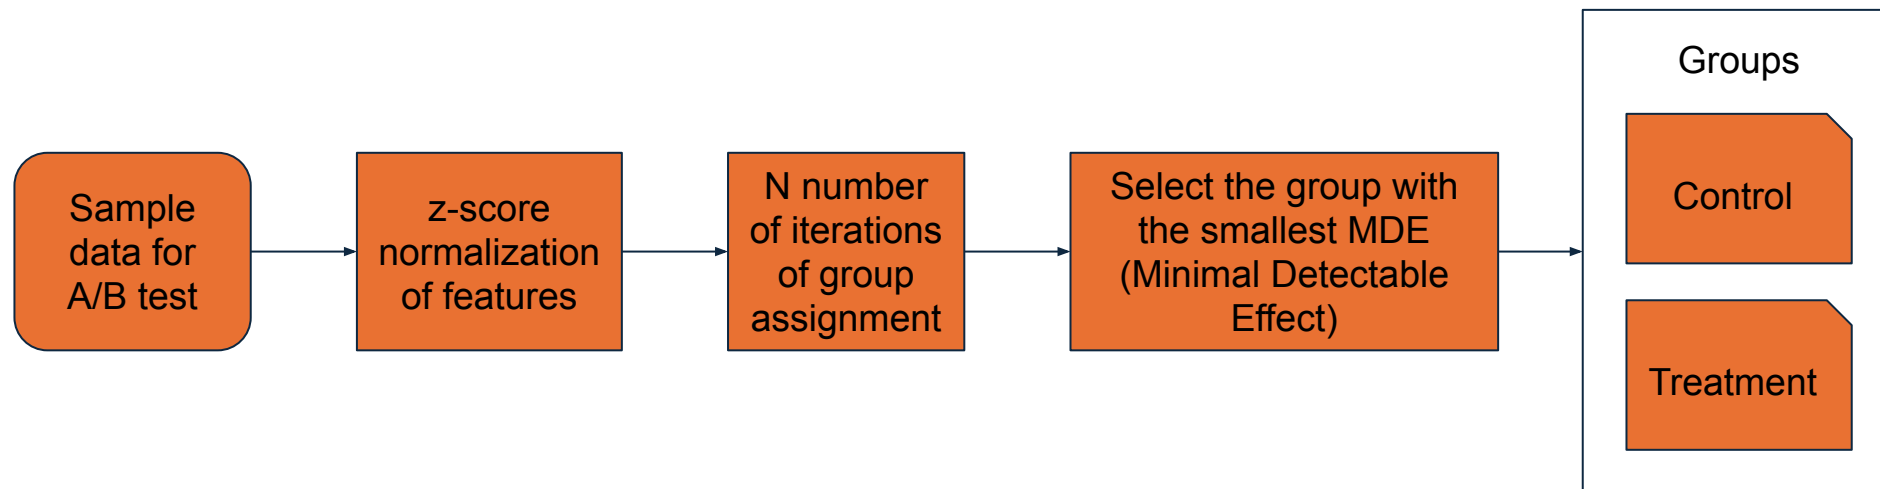

Controlled Distribution

Part of internal A/B testing package developed at Allegro

Key features

- Our recommended approach especially for limited sample size, so that random distributional differences don't skew the results
- Smart group assignment: Distributes products into groups while maintaining balanced metric distributions
 - Sampling-based approach to minimize distributional differences of normalized group metric means with Euclidean distance
- Input based slice aware splitting: Handles splits across multiple slicing dimensions (i.e category)
- Using Monte Carlo sampling, control and treatment group attributes like GMV, profit, and category are nearly identical

A/B test Overview

Product level A/B testing

Average GMV per group

- **Consistent growth** in GMV translating into **significant yearly impact** on the whole Allegro level.
- Generated GMV is profitable - incremental sales pay off the subsidy investments.
- The Evaluation was based on bootstrapping due to several advantages:
 - No distributional assumptions
 - Particularly useful when you are dealing with a limited sample size
 - Confidence intervals are derived from the N iterations of resampled data
 - Each bootstrap iteration captures around 63–65% of unique data points, but with enough iterations, you can eventually cover the entire dataset
